

# **Individual tree models**

## **growth and calculus modules**

# Individual tree models - state variables

## ✗ The most common principal variables

- ✓ Dominant height (stand level variable)
- ✓ Diameter at breast height
- ✓ Tree height may also be a principal variable

## ✗ Derived variables

- ✓ Tree: total height and height to the base of the crown, tree volume, tree biomass (total and per component)
- ✓ Stand: all variables except dominant height

# Calculus of stand variables

## ✗ Example for stand volume

- ✓ Prediction of tree mortality and of diameter tree growth for each tree
- ✓ Prediction of tree height with a height-diameter curve (or, eventually prediction of height growth) for each tree
- ✓ Prediction of the volume for each tree with a volume equation
- ✓ Calculus of plot volume by summing up the volume of every tree in the plot
- ✓ Expansion to the ha, using the respective expansion factor (10000/plot area) - many models use 1 ha plots therefore this step is not needed

# Modeling individual tree dbh growth

- ✗ Several methods have been used to model tree dbh growth, which may be classified as:
  - ✓ Linear or nonlinear regression models using  $i_d$  or  $i_g$  as dependent variable
  - ✓ Difference equations ( $d_{t2}$  or  $g_{t2}$  as dependent variable)
  - ✓ Growth potential x modifier type models
    - Dependent variable is usually  $i_d$  or  $i_g$

# Linear regression models - examples

## ✕ Examples:

$$\ln(i_{g,10}) = \beta_0 + \beta_1 \ln(d) + \beta_2 \ln(\text{CCF}) + \beta_3 \ln\left(\frac{d}{dg}\right) + \beta_4 \ln(S) + \beta_5 \text{ALT}$$

$$\ln(i_{g,10}) = \beta_0 + \beta_1 \ln(d) + \beta_2 \ln(\text{CCF}) + \beta_3 \ln\left(\frac{d}{dg}\right) + \beta_4 \ln\left(\frac{1}{t}\right)$$

# Difference equations - examples

- ✗ Dbh growth model for dominant cork oak trees (without age explicit (200 is an asymptote))

$$d_{t+a} = 200 \left( 1 - e^{-(-0.00093 + 0.000275 S) a} \left( 1 - \left( \frac{d_t}{200} \right)^{1.1207} \right) \right)^{\frac{1}{1.1207}}$$

The diagram illustrates the relationship between the variables in the equation. An orange box labeled "Site index" has an orange arrow pointing upwards to the term  $S$  in the exponent of the equation. A green box labeled "Tree dimension" has a green arrow pointing upwards to the term  $d_t$  in the inner parentheses of the equation.

# Potential X modifier type models

✗ These models are based on the assumption that individual tree growth may be modeled as:

$i_d = i_d$  potential X modifier

- The  $i_d$  potential represents the growth of a tree of the same size that grows without limitations
- The modifier is a function that takes values between 0 and 1, defining growth restrictions (usually competition but other factors may also be taken into account)

# Potential X modifier type models

- ✗ There are different concepts of potential growth that have been used:
  - ✓ Maximum growth that a tree of the same species and size/age may attain under optimum conditions in terms of water and nutrients
  - ✓ Maximum observed growth for a tree of the same species and size
  - ✓ Maximum growth of the trees in the same plot (growth of the dominant trees)

# Potential X modifier type models - example

## ✕ GLOB-tree model - potential growth

$$ddom_{t2} = A \left( \frac{ddom_{t1}}{A} \right)^{(t1/t2)^n} = (31.6761 + 1.2067 S) \left( \frac{ddom_{t1}}{31.6761 + 1.2067 S} \right)^{(t1/t2)^{0.4905}}$$

$$ipot_d = ddom_{t2} - ddom_{t1}$$

# Potential X modifier type models - example

## ✕ GLOB-tree model - modifier

$$i_d = ipot_d \times \frac{1}{1 + e^{a_0 + a_1 R_{\bar{g}} + a_2 100/N + a_3 cr}} \times e^{b_1 PDU} \times \left( 1 - e^{c_0} + c_1 APA \right)$$

The diagram illustrates the GLOB-tree model equation with the following components and their relationships:

- Stand density** (orange box) points to the denominator term  $1 + e^{a_0 + a_1 R_{\bar{g}} + a_2 100/N + a_3 cr}$ .
- Distance independent CI** (light green box) points to the term  $R_{\bar{g}}$  in the denominator.
- Unilateral distance dependent CI** (dark green box) points to the term  $PDU$  in the exponent of the second term.
- distance dependent CI** (dark green box) points to the term  $APA$  in the third term.

The formula for  $R_{\bar{g}}$  is given as:

$$R_{\bar{g}} = \frac{gi}{\bar{g}}$$

# Height prediction - example

## GLOB-tree model

### ✗ Young stands ( $t < 4$ years)

$$h = 1.30 + hdom \left( 1 + (-0.43487 - 0.0108 t + 0.09772 hdom - 0.06021 dg) e^{-0.04864 hdom} \right) \left( 1 - e^{-1.58926 \frac{d}{hdom}} \right)$$

### ✗ Adult stands ( $t > 4$ years)

$$h = hdom \left( 1 + \left( 0.10694 + 0.02916 \frac{N}{1000} - 0.00176 d_{max} \right) e^{0.03540 hdom} \right) \left( 1 - e^{-1.81117 \frac{d}{hdom}} \right)$$

# Crown variables - examples

## ✗ GLOB-tree model - crown ratio

$$cr = \frac{1}{\left[ 1 + e^{-\left( -5.76111 + 12.334131/t - 0.27179 N/1000 - 0.17543 hdom + 0.20559 d \right)} \right]^{1/6}}$$

The diagram illustrates the GLOB-tree model equation for crown ratio (cr). The equation is:

$$cr = \frac{1}{\left[ 1 + e^{-\left( -5.76111 + 12.334131/t - 0.27179 N/1000 - 0.17543 hdom + 0.20559 d \right)} \right]^{1/6}}$$

Three variables are highlighted with arrows:

- Tree age** (t) is highlighted in a green box.
- Stand density** (N) is highlighted in an orange box.
- Tree dimension** (d) is highlighted in a green box.

# Predicting tree mortality - examples

## ✕ GLOB-tree model

$$P(\text{tree dies}) = \frac{e^{2.2735 - 0.0469 G + 1.5340 R_{\bar{g}} + 0.2841 d}}{1 + e^{2.2735 - 0.0469 G + 1.5340 R_{\bar{g}} + 0.2841 d}}$$
